Search Strategies

Petros Papapanagiotou

Informatics 2D: Reasoning and Agents **Lecture 3**

Search strategies

A search strategy is defined by picking the order of node expansion.

• Nodes are taken from the **frontier**.

Evaluating search strategies

completeness: does it always find a solution if one exists?

time complexity: number of nodes generated / expanded

space complexity: maximum number of nodes in memory

optimality: does it always find a least-cost solution?

Time and space complexity are measured in terms of:

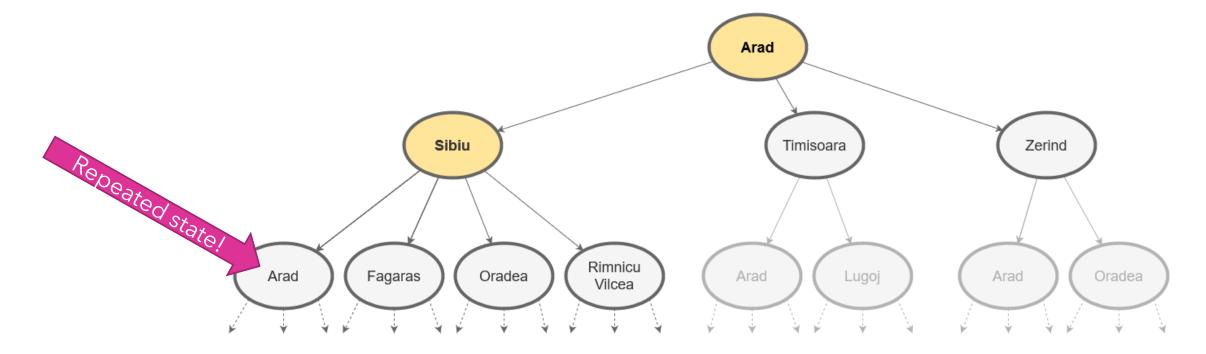

- **b**: maximum branching factor of the search tree
- **d**: depth of the least-cost solution
- m: maximum depth of the state space (may be ∞)

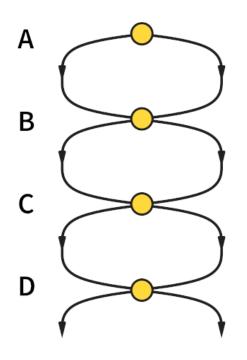

Recall: Tree Search

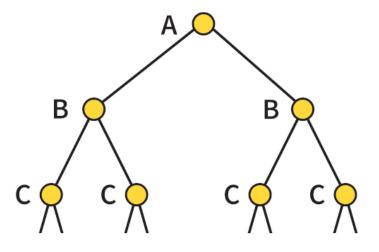

function TREE-SEARCH(*problem*) **returns** a solution, or failure initialize the frontier using the initial state of *problem* **loop do**

if the frontier is empty then return failure choose a leaf node and remove it from the frontier

if the node contains a goal state **then return** the corresponding solution expand the chosen node, adding the resulting nodes to the frontier

Repeated states

Failure to detect repeated states can turn a **linear** problem into an **exponential** one!

function GRAPH-SEARCH(problem) returns a solution, or failure initialize the frontier using the initial state of problem initialize the explored set to be empty loop do

if the frontier is empty then return failure
choose a leaf node and remove it from the frontier
if the node contains a goal state then return the corresponding solution
add the node to the explored set
expand the chosen node, adding the resulting nodes to the frontier
only if not in the frontier or explored set

Graph search

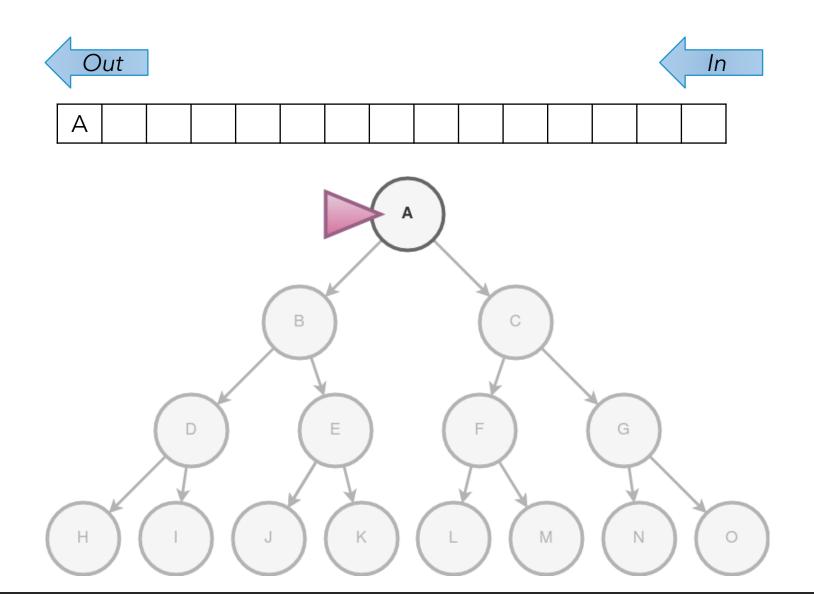

Augment TREE-SEARCH with a new data-structure:

- the **explored set** (closed list), which remembers every expanded node
- newly expanded nodes already in explored set are discarded

Expand **shallowest** unexpanded node

Implementation:

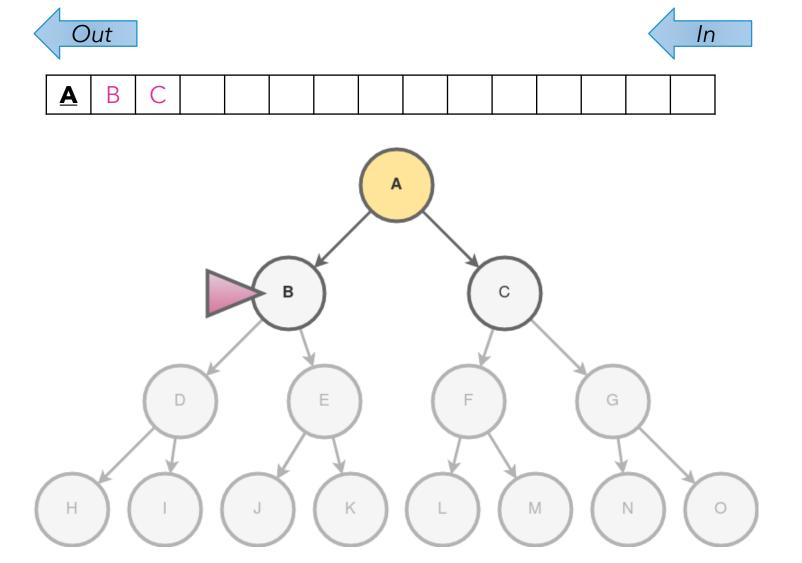

frontier is a FIFO queue,
 i.e., new successors go at
 end

Expand **shallowest** unexpanded node

Implementation:

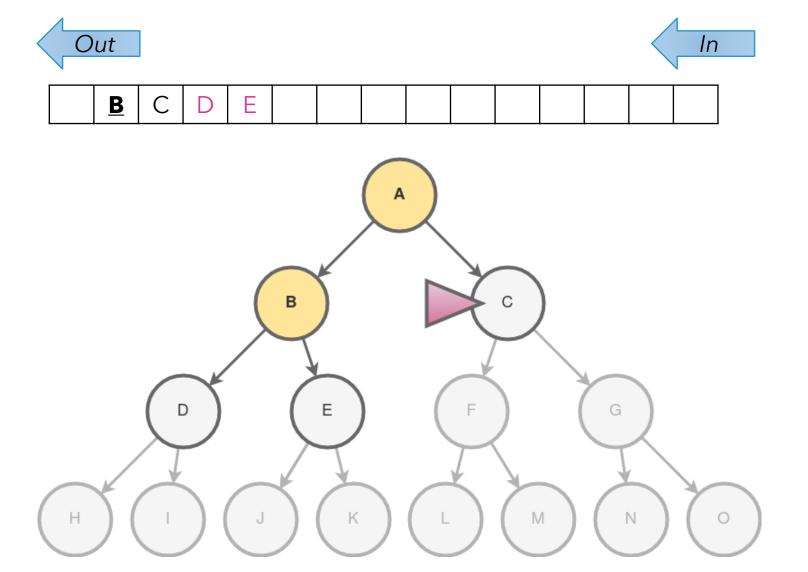

frontier is a FIFO queue,
 i.e., new successors go at
 end

Expand **shallowest** unexpanded node

Implementation:

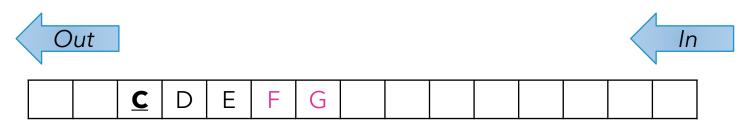

frontier is a FIFO queue,
 i.e., new successors go at
 end

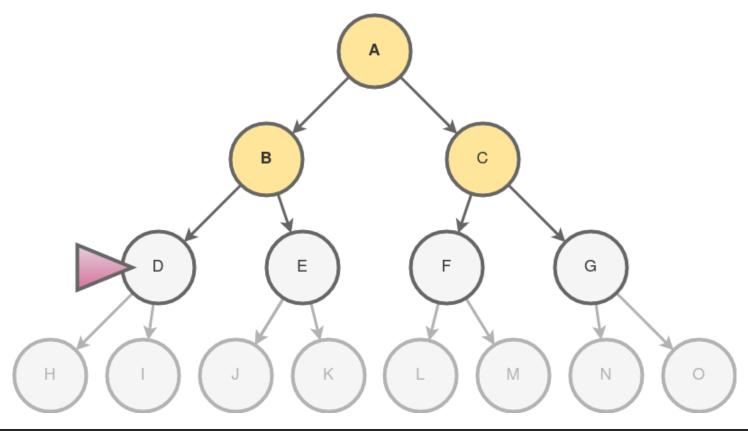

Expand **shallowest** unexpanded node

Implementation:

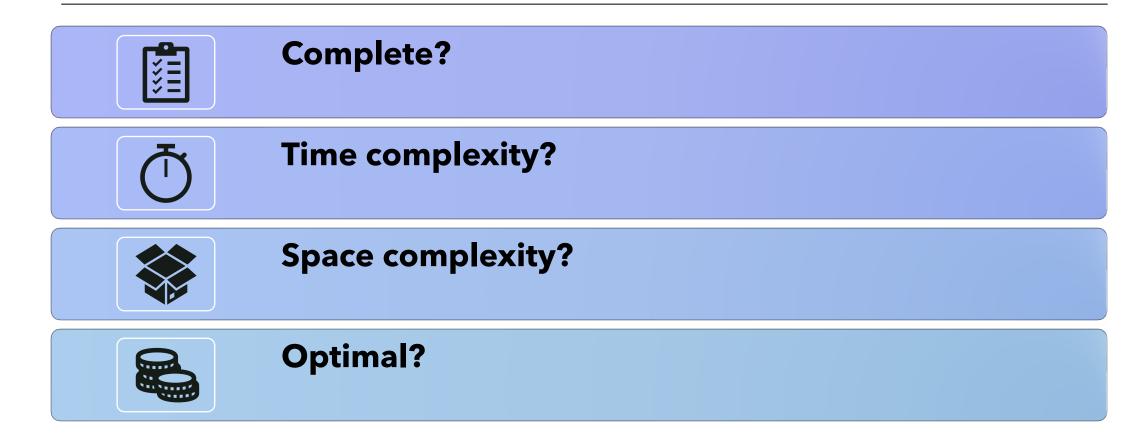

frontier is a FIFO queue,
 i.e., new successors go at
 end

```
function Breadth-First-Search(problem) returns a solution, or failure
  node \leftarrow a node with STATE = problem.INITIAL-STATE, PATH-COST = 0
  if problem.GOAL-TEST(node.STATE) then return SOLUTION(node)
  frontier \leftarrow a FIFO queue with node as the only element
  explored \leftarrow an empty set
  loop do
      if EMPTY?(frontier) then return failure
      node \leftarrow Pop(frontier) /* chooses the shallowest node in frontier */
      add node.STATE to explored
      for each action in problem. ACTIONS (node. STATE) do
          child \leftarrow CHILD-NODE(problem, node, action)
         if child.STATE is not in explored or frontier then
             if problem.GOAL-TEST(child.STATE) then return SOLUTION(child)
             frontier \leftarrow INSERT(child, frontier)
```

Breadthfirst search algorithm

Complete?

Yes (if b is finite)

Time complexity?

Space complexity?

Optimal?

Complete?

Yes (if b is finite)

Time complexity?

 $b+b^2+b^3+...+b^d = O(b^d)$ (worst-case)

Space complexity?

Optimal?

Complete?

Yes (if b is finite)

Time complexity?

 $b+b^2+b^3+...+b^d=O(b^d)$ (worst-case)

Space complexity?

 $O(b^d)$ (keeps every node in memory)

Optimal?

Complete?

Yes (if b is finite)

Time complexity?

 $b+b^2+b^3+...+b^d=O(b^d)$ (worst-case)

Space complexity?

 $O(b^d)$ (keeps every node in memory)

Optimal?

Yes (if cost = 1 per step)

Complete?

Yes (if b is finite)

Time complexity?

 $b+b^2+b^3+...+b^d=O(b^d)$ (worst-case)

Space complexity?

 $O(b^d)$ (keeps every node in memory)

Optimal?

Yes (if cost = 1 per step)

then optimal solution is closest to start!

Complete?

Yes (if b is finite)

Time complexity?

 $b+b^2+b^3+...+b^d=O(b^d)$ (worst-case)

Space complexity?

 $O(b^d)$ (keeps every node in memory)

Optimal?

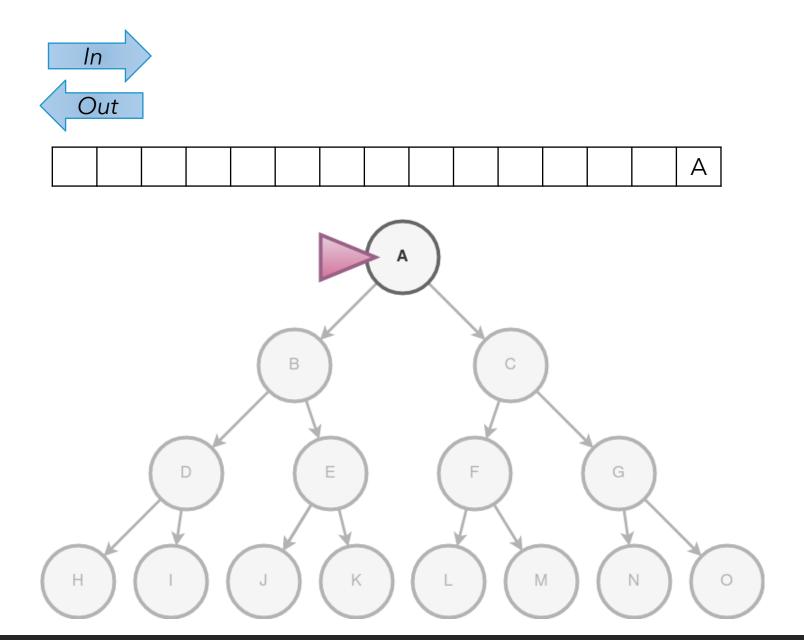

Yes (if cost = 1 per step)

Space is the bigger problem (more than time)

Expand **deepest** unexpanded node

Implementation:

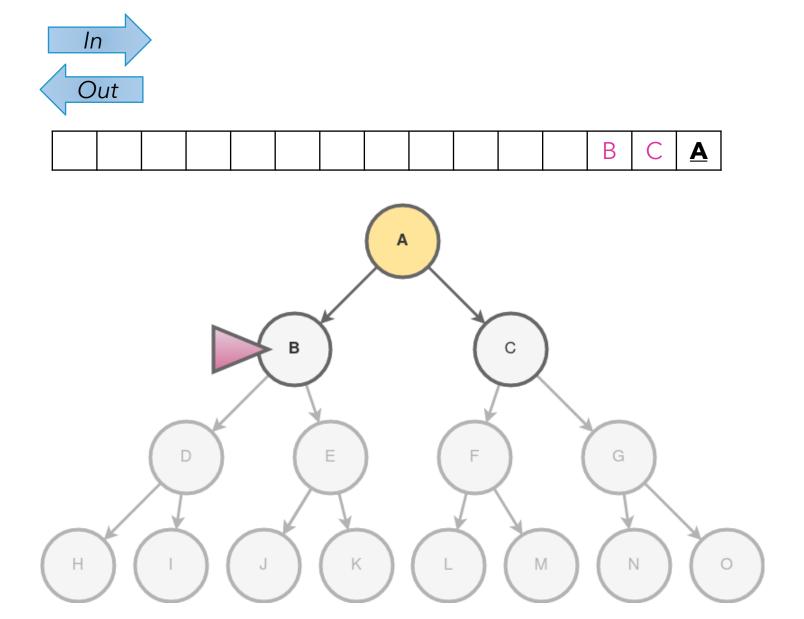

frontier is a LIFO queue,
 i.e., new successors go at
 front

Expand **deepest** unexpanded node

Implementation:

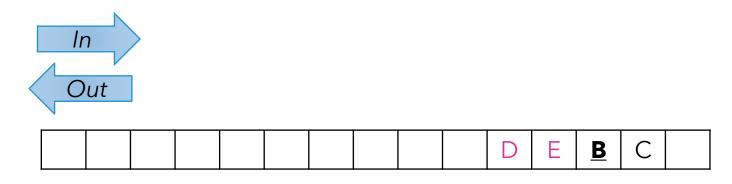

frontier is a LIFO queue,
 i.e., new successors go at
 front

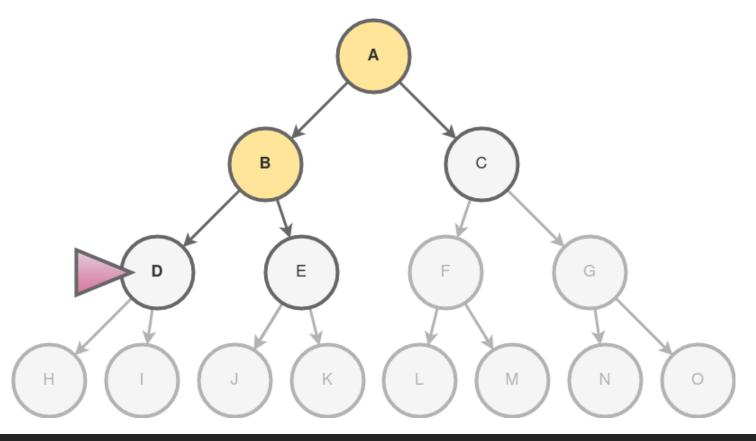

Expand **deepest** unexpanded node

Implementation:

Complete?

No: fails in infinite-depth spaces, spaces with loops

Time complexity?

Space complexity?

Optimal?

Complete?

No: fails in infinite-depth spaces, spaces with loops

Time complexity?

avoid repeated states along path; complete in finite spaces

Space complexity?

Optimal?

Complete?

No: fails in infinite-depth spaces, spaces with loops

Time complexity?

 $O(b^m)$: terrible if m is much larger than d

Space complexity?

Optimal?

Complete?

No: fails in infinite-depth spaces, spaces with loops

Time complexity?

 $O(b^m)$: terrible if m is much larger than d

Space complexity?

If solutions are dense, depth-first may be much faster than breadth-first!

Optimal?

Complete?

No: fails in infinite-depth spaces, spaces with loops

Time complexity?

 $O(b^m)$: terrible if m is much larger than d

Space complexity?

O(bm), i.e., linear space!

Optimal?

Properties of depth-first search

Complete?

No: fails in infinite-depth spaces, spaces with loops

Time complexity?

 $O(b^m)$: terrible if m is much larger than d

Space complexity?

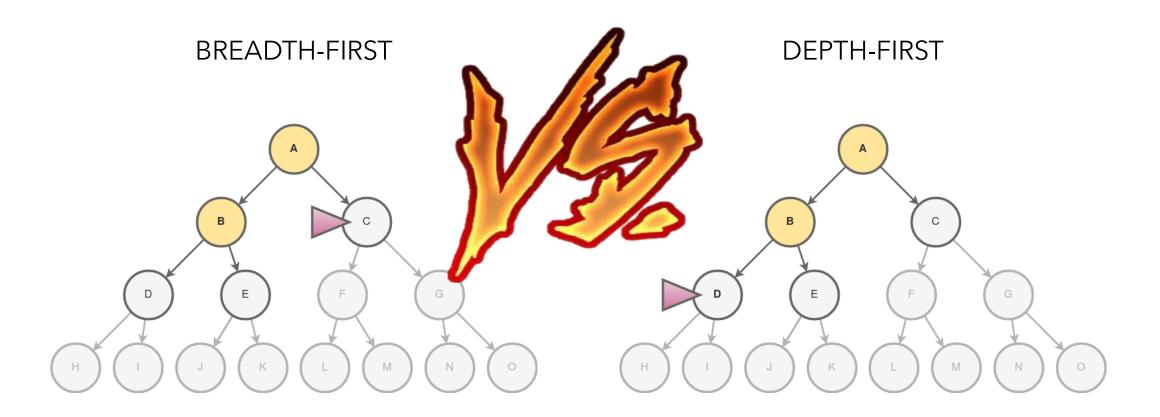

O(bm), i.e., linear space!

Optimal?

No

Mid-Lecture Exercise

Mid-Lecture Exercise

BREADTH-FIRST

When optimal solutions are important.

DEPTH-FIRST

 When solutions are dense and low-cost is important, especially space costs.

Iterative deepening search

... or how to improve depth-first search

function DEPTH-LIMITED-SEARCH(problem, limit) returns a solution, or failure/cutoff return RECURSIVE-DLS(MAKE-NODE(problem.INITIAL-STATE), problem, limit) function RECURSIVE-DLS(node, problem, limit) returns a solution, or failure/cutoff if problem.GOAL-TEST(node.STATE) then return SOLUTION(node) else if limit = 0 then return cutoff else cutoff_occurred? ← false for each action in problem.ACTIONS(node.STATE) do child ← CHILD-NODE(problem, node, action) result ← RECURSIVE-DLS(child, problem, limit − 1) if result = cutoff then cutoff_occurred? ← true else if result ≠ failure then return result if cutoff_occurred? then return cutoff else return failure

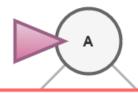

Depth-limited search

This is depth-first search with depth limit *l*, i.e., nodes at depth *l* have no successors

Iterative deepening search

```
function Iterative-Deepening-Search(problem) returns a solution, or failure
   for depth = 0 to ∞ do
      result ← Depth-Limited-Search(problem, depth)
      if result ≠ cutoff then return result
```

Iterative deepening search I = 0

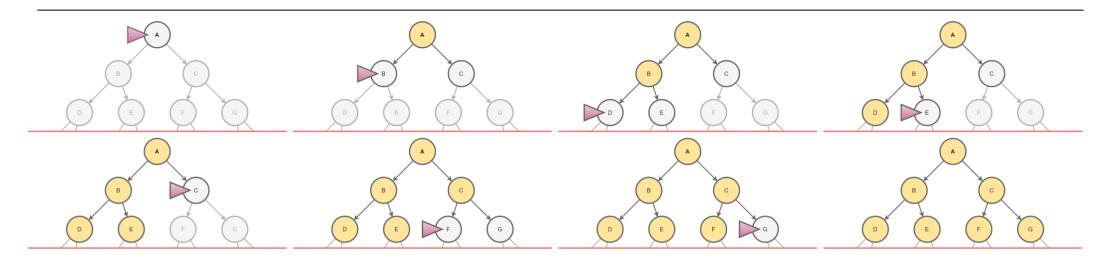

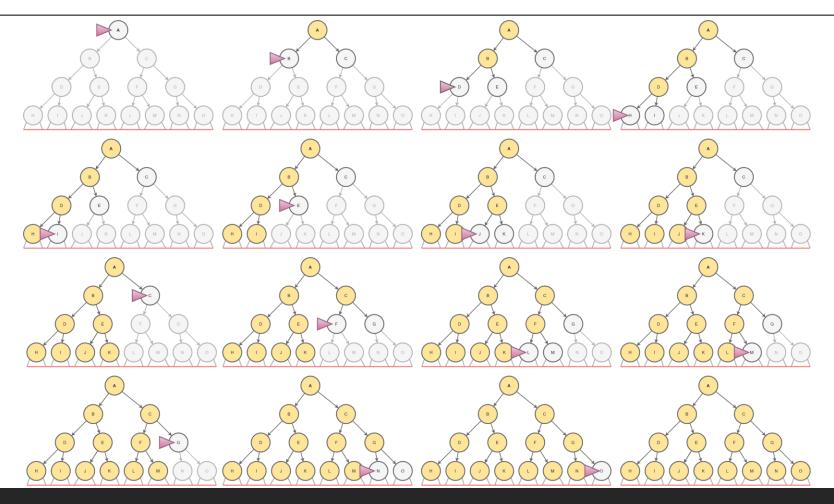

Iterative deepening search l = 1

Iterative deepening search l=2

Iterative deepening search l = 3

Iterative deepening search

Number of nodes generated in an iterative deepening search to depth d with branching factor b:

$$N_{IDS} = (d)b + (d-1)b^2 + ... + (2)b^{d-1} + (1)b^d$$

Some cost associated with generating upper levels multiple times

Example: For b = 10, d = 5,

$$\circ$$
 N_{BES} = 10 + 100 + 1,000 + 10,000 + 100,000 = 111,110

$$\circ$$
 N_{IDS} = 50 + 400 + 3,000 + 20,000 + 100,000 = 123,450

Overhead = (123,450 - 111,110)/111,110 = 11%

Complete?

Yes

Time complexity?

$$(d)b + (d-1)b^2 + ... + (1)b^d = O(b^d)$$

Space complexity?

Optimal?

Complete?

Yes

Time complexity?

$$(d)b + (d-1)b^2 + ... + (1)b^d = O(b^d)$$

Space complexity?

O(bd)

Optimal?

Complete?

Yes

Time complexity?

$$(d)b + (d-1)b^2 + ... + (1)b^d = O(b^d)$$

Space complexity?

O(bd)

Optimal?

Yes, if step cost = 1

Criterion	Breadth-	Uniform-	Depth-	Depth-	Iterative
	First	Cost	First	Limited	Deepening
Complete?	Yes	Yes	No	No	Yes
Time	$O(b^{d+1})$	$O(b^{\lceil C^*/\epsilon ceil})$	$O(b^m)$	$O(b^l)$	$O(b^d)$
Space	$O(b^{d+1})$	$O(b^{\lceil C^*/\epsilon ceil})$	O(bm)	O(bl)	O(bd)
Optimal?	Yes	Yes	No	No	Yes

Summary of algorithms

Summary

Variety of uninformed search strategies:

breadth-first, depth-first, iterative deepening

Iterative deepening search uses only linear space and not much more time than other uninformed algorithms

Why?

- Very common algorithms.
- Used whenever we are looking for a path between 2 points in a tree or graph.
 - Anywhere from games to programming languages.
- Properties matter!
- e.g. time or space complexity may be important depending on application.
- Understanding which algorithm to use in what circumstances.
